Evaluating a Hypothesis

Once we have done some trouble shooting for errors in our predictions by:

- · Getting more training examples
- Trying smaller sets of features
- Trying additional features
- Trying polynomial features
- Increasing or decreasing λ

We can move on to evaluate our new hypothesis.

A hypothesis may have a low error for the training examples but still be inaccurate (because of overfitting). Thus, to evaluate a hypothesis, given a dataset of training examples, we can split up the data into two sets: a **training set** and a **test set**. Typically, the training set consists of 70 % of your data and the test set is the remaining 30 %.

The new procedure using these two sets is then:

- 1. Learn Θ and minimize $J_{train}\left(\Theta\right)$ using the training set
- 2. Compute the test set error $J_{test}\left(\Theta\right)$

The test set error

1. For linear regression:
$$J_{test}\left(\Theta
ight) = rac{1}{2m_{test}} \sum_{i=1}^{m_{test}} \left(h_{\Theta}\left(x_{test}^{(i)}
ight) - y_{test}^{(i)}
ight)^2$$

2. For classification ~ Misclassification error (aka 0/1 misclassification error):

$$err\left(h_{\Theta}\left(x
ight),y
ight)=rac{1}{0} \quad ext{if } h_{\Theta}\left(x
ight)\geq0.5 \ and \ y=0 \ or \ h_{\Theta}\left(x
ight)<0.5 \ and \ y=1 \ otherwise$$

This gives us a binary 0 or 1 error result based on a misclassification. The average test error for the test set is:

$$\text{Test Error} = \frac{1}{m_{test}} \sum_{i=1}^{m_{test}} \textit{err} \left(h_{\Theta}\left(x_{test}^{(i)}\right), y_{test}^{(i)}\right)$$

This gives us the proportion of the test data that was misclassified.
