Regularized Logistic Regression

We can regularize logistic regression in a similar way that we regularize linear regression. As a result, we can avoid overfitting. The following image shows how the regularized function, displayed by the pink line, is less likely to overfit than the non-regularized function represented by the blue line:

Regularized logistic regression.

$$h_{\theta}(x) = g(\theta_0 + \theta_1 x_1 + \theta_2 x_1^2 + \theta_3 x_1^2 x_2 + \theta_4 x_1^2 x_2^2 + \theta_5 x_1^2 x_2^3 + \dots)$$

Cost Function

Recall that our cost function for logistic regression was:

$$J\left(heta
ight) = -rac{1}{m}\sum_{i=1}^{m}[y^{(i)}\ \log\left(h_{ heta}\left(x^{(i)}
ight)
ight) + \left(1-y^{(i)}
ight)\ \log\left(1-h_{ heta}\left(x^{(i)}
ight)
ight)]$$

We can regularize this equation by adding a term to the end:

$$J(heta) = -rac{1}{m} \sum_{i=1}^{m} [y^{(i)} \; \log \left(h_{ heta}\left(x^{(i)}
ight)
ight) + \left(1-y^{(i)}
ight) \; \log \left(1-h_{ heta}\left(x^{(i)}
ight)
ight)] + rac{\lambda}{2m} \sum_{j=1}^{n} heta_{j}^{2}$$

The second sum, $\sum_{j=1}^n \theta_j^2$ means to explicitly exclude the bias term, θ_0 . I.e. the θ vector is indexed from 0 to n (holding n+1 values, θ_0 through θ_n), and this sum explicitly skips θ_0 , by running from 1 to n, skipping 0. Thus, when computing the equation, we should continuously update the two following equations:

Gradient descent

Repeat {
$$\Rightarrow \quad \theta_0 := \theta_0 - \alpha \frac{1}{m} \sum_{i=1}^m (h_\theta(x^{(i)}) - y^{(i)}) x_0^{(i)}$$

$$\Rightarrow \quad \theta_j := \theta_j - \alpha \underbrace{\left[\frac{1}{m} \sum_{i=1}^m (h_\theta(x^{(i)}) - y^{(i)}) x_j^{(i)} + \frac{\lambda}{m} \odot_j \right]}_{\left(j = \mathbf{X}, 1, 2, 3, \dots, n\right)}$$

$$\underbrace{\left[\frac{\lambda}{\partial \Theta_j} \underbrace{\Xi(\Theta)}_{i} \right]}_{\left(0, \dots, \infty_n\right)}$$
